

# BAYESIAN ANALYSIS OF VARs, STATE-SPACE MODELS AND DSGEs PART V - DSGEs

Mattias Villani

**Division of Statistics and Machine Learning  
Department of Computer and Information Science  
Linköping University**

# LECTURE OVERVIEW

- ▶ A DSGE model
- ▶ The likelihood function
- ▶ Bayesian inference
- ▶ Words of wisdom

INÅNS | RÄNTAN

## Ekvationer på hal is

Riksbankens nylanserade ekonomiska modell som ska underlätta prognosarbetet och ligga till grund för räntepolitiken visar att dagens svenska styrränta på två procent är alldeles för låg. Nu är risken stor att riksbanksdirektionen faktiskt litat på modellresultaten och därför inte har sänkt räntan.

en stora faran för svenska bolånare kommer inte från att inflationen plötsligt ta ta fart, lönerörelsen skena eller att konjunkturen blir så stark att Riksbanken tvingas höja räntan.

Nej, den stora faran tycks vara att riksbanksledningen börjar lita på resultaten än den ekonomiska modell som ban-

der den här perioden försvunnit. Nu tycks det som om Riksbanken i högre grad har satsat på akademisk kompetens i stället för prognoskunnande när man nyrekryterat med superakademikern Anders Vredin i spetsen. Resultatet av den satsningen syns i den ekonomiska modell (DSGE) som den ekonomiska avdelningen på Riksbank-

# A DSGE MODEL (RAMSES I)

- ▶ **Small open economy**
- ▶ **15** observed variables
- ▶ **Many state variables**
- ▶ **> 50** 'deep' parameters.
- ▶ **Model parameters:**
  - ▶ Steady state parameters (calibrated in Ramses)
  - ▶ **Frictions:**  $\xi_w, \xi_d, b, \dots$
  - ▶ **Shock processes:**  $\rho_z, \sigma_z^2, \dots$
  - ▶ **Policy parameters**  $r_\pi, \sigma_R, \dots$
  - ▶ VAR model for the exogenous variables (estimated separately)

# PARAMETERS IN RAMSES I

Parameter	Prior distribution		
	Type	Mean	Std. dev./df
Calvo wages $\tilde{\epsilon}_w$	beta	0.750	0.050

# THE LIKELIHOOD FUNCTION

- ▶ Given a value for the parameter vector  $\theta = \tilde{\theta}$ , do the following:
  - ▶ **Compute the steady-state** of the model.
  - ▶ **Solve the log-linearized model** (e.g. AIM or Sims)
  - ▶ Set up **state-space model**

$$\tilde{\zeta}_t = \mathbf{F}(\tilde{\theta})\tilde{\zeta}_{t-1} + \mathbf{v}_t, \quad \mathbf{v}_t \stackrel{iid}{\sim} N(0, \mathbf{Q}(\tilde{\theta})) \quad (\text{state transition equation})$$

$$\mathbf{y}_t = \mathbf{H}(\tilde{\theta})'\tilde{\zeta}_t + \mathbf{w}_t, \quad \mathbf{w}_t \stackrel{iid}{\sim} N(0, \mathbf{R}) \quad (\text{measurement equation})$$

with

- ▶ Transitions for latent states (e.g. technology shocks)
  - ▶ Matching states to observed variables through measurement equations
  - ▶ Decide on measurement errors ( $\mathbf{R}$ ) or estimate them.
- ▶ **Iterate the Kalman filter** forward to compute the (marginalized) likelihood:

$$p(\mathbf{y}_{1:T} | \mathbf{F}(\theta), \mathbf{H}(\theta), \mathbf{Q}(\theta), \mathbf{R}(\theta))$$

# BAYESIAN ANALYSIS OF DSGEs

- ▶ **Set up priors** for all model parameters. Use micro data, historical macro data before the current dataset, data from other countries, expert opinions, Larry Christiano's parameter values ...
- ▶ **Bayes' theorem** (posterior  $\propto$  likelihood  $\times$  prior)

$$p(\theta | \mathbf{y}_{1:T}) \propto p(\mathbf{y}_{1:T} | \mathbf{F}(\theta), \mathbf{H}(\theta), \mathbf{Q}(\theta), \mathbf{R}(\theta)) \cdot p(\theta)$$

- ▶ **Optimize** numerically (fminunc with BFGS update of Hessian) to obtain  $\hat{\theta}_{mode}$  and Hessian  $H$  at the mode.
- ▶ Initialize MCMC at  $\hat{\theta}_{mode}$  and run **random walk Metropolis algorithm** with proposal

$$\theta_p | \theta^{(i-1)} \sim N\left(\theta^{(i-1)}, c \cdot \Sigma\right)$$

with  $\Sigma = -H^{-1}$  and  $c$  tuned so that accept. prob. is roughly 0.25.

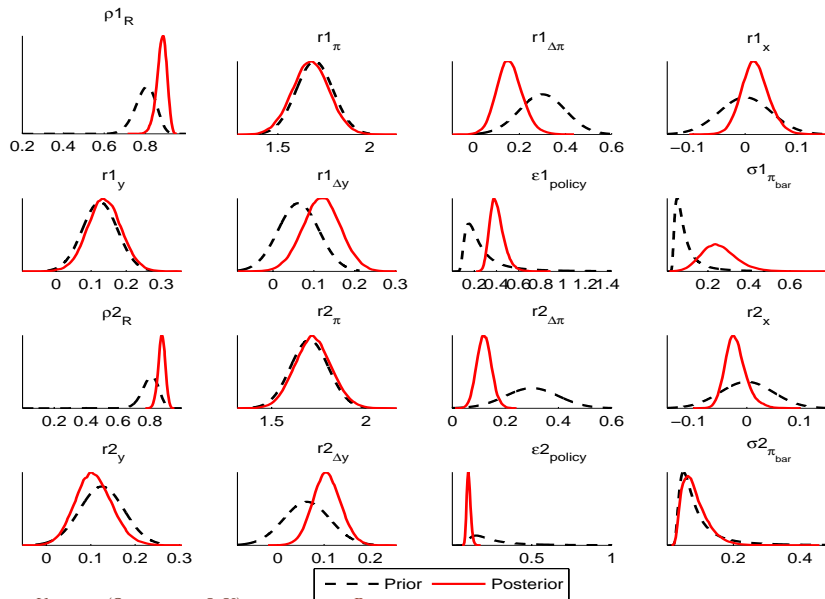

- ▶ **Check for convergence.**

# BAYESIAN ANALYSIS OF DSGEs

- ▶ Compute functions of the parameter draws to approximate the posterior of other quantities (**IRs**).
- ▶ **Compute marginal likelihoods** with the modified Harmonic estimator (RWM) or Chib-Jeliazkov (IMH). Model comparison. Model averaging.
- ▶ **Predictions.**
- ▶ **Posterior predictive checks.**

# PRIORS AND POSTERIORIS - POLICY PARAMETERS

# PRIOR SENSITIVITY

Table A.6: Prior sensitivity

# IMPULSE RESPONSES DSGE

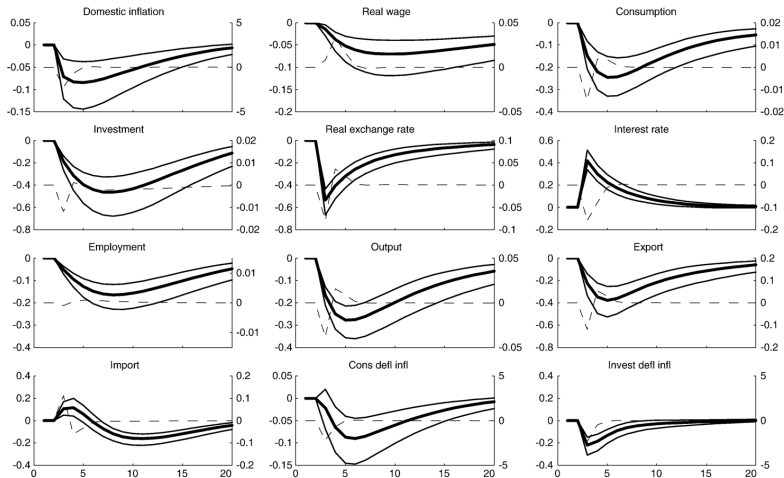

Fig. 3. Impulse responses (posterior median and 95% uncertainty intervals) to a one standard deviation monetary policy shock. Note: Benchmark (solid, left axis) and flexible prices and wages (dashed, right axis).

# IMPULSE RESPONSES DSGE vs BVARs

# BAYESIAN PREDICTION WITH DSGEs

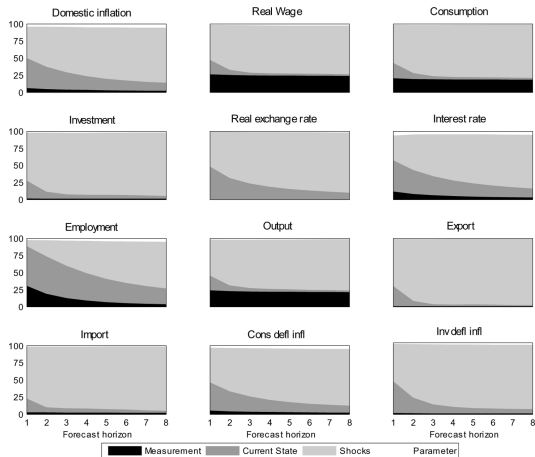

- ▶ **Predictive distribution**  $p(\mathbf{y}_{T+1:T+h}|\mathbf{y}_{1:T})$  by simulation
  - ▶ Simulate a **parameter vector**  $\tilde{\theta}$  from the posterior  $p(\theta|\mathbf{y}_{1:T})$  by MCMC.
  - ▶ Draw the **current state**  $\xi_T \sim N(\xi_{T|T}, P_{T|T})$
  - ▶ Simulate **future states** for  $t = T+1, \dots, T+h$  from

$$\xi_t = \mathbf{F}(\tilde{\theta})\xi_{t-1} + \mathbf{v}_t, \quad \mathbf{v}_t \stackrel{iid}{\sim} N(0, \mathbf{Q}(\tilde{\theta}))$$

- ▶ Simulate the **observed variables** for  $t = T+1, \dots, T+h$  conditional on the simulated states:

$$\mathbf{y}_t = \mathbf{H}(\tilde{\theta})'\xi_t + \mathbf{w}_t, \quad \mathbf{w}_t \stackrel{iid}{\sim} N(0, \mathbf{R})$$

# BAYESIAN PREDICTION WITH DSGEs

**FIGURE 4** Decomposition of the forecast uncertainty. The subgraphs display the relative contribution to the predictive variances of the observed variables at different forecast horizons.

# FORECASTS DSGE

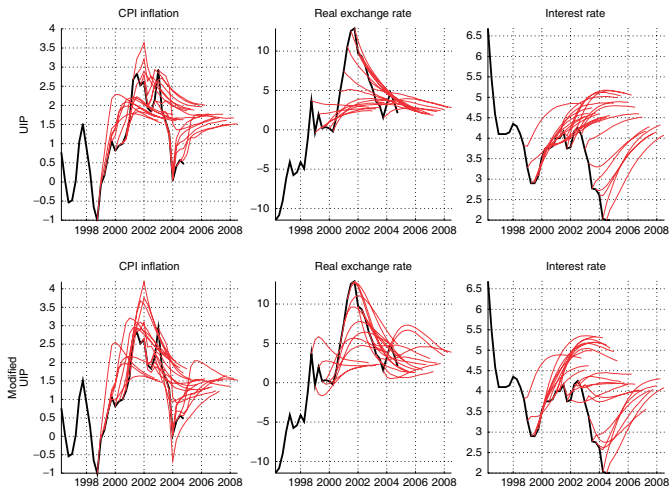

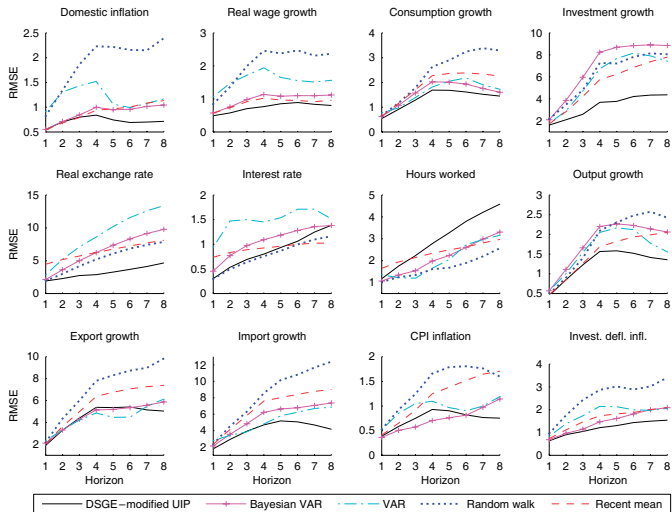

Fig. 3. Actual data (thick line) and forecasts (thin lines) 1999Q1–2004Q4 from the DSGE using different UIP specifications.

# FORECAST EVALUATION DSGE 1999Q1-2004Q4

# PRACTICAL OPTIMIZATION

- ▶ Numerical optimization in DSGEs can be hard.
- ▶ RAMSES I started out with **fminsearch**. Derivative-free optimizer. Slow, but robust.
- ▶ Once fminsearch has obtained a decent point, switch to **fminunc** with **BFGS** update of Hessian. Less robust, but fast and reliable enough when you are not too far from mode.
- ▶ Repeat the fminsearch/fminunc procedure with **different starting values** to check for local modes.
- ▶ Once the mode has been reached in a benchmark model, **alternative specifications** can use that mode as good initial values and converges fast.

# PRACTICAL OPTIMIZATION

## ► Check the quality of the Hessian by:

1. Computing the exact log posterior by perturbing each parameter (one at a time). This produces a **slice** of the log posterior along each of the parameters.
2. Compute the following approximation of the posterior from the optimization output:

$$\theta | \mathbf{y}_{1:T} \sim N(\hat{\theta}_{mode}, \Sigma)$$

where  $\Sigma = -H^{-1}$ .

3. **Slice the approximate posterior along the  $j$ th parameter**

$$p(\theta_j | \mathbf{y}_{1:T}) \approx N(\hat{\theta}_{j,mode}, s_j^2)$$

where  $s_j^2$  is the (approximate) posterior variance of  $\theta_j$  **conditional on** the other parameters being at their mode (computed from  $\Sigma$  by a simple formula).

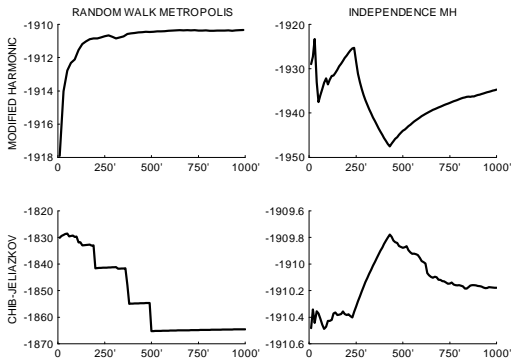

4. Plot the slices from 1 and 3 in the same graph, one for each parameter.

# SLICING THE POSTERIOR

# MARGINAL LIKELIHOOD ESTIMATION

- ▶ The best marginal likelihood estimator depends on the MCMC algorithm [1]
  - ▶ **Modified harmonic estimator** works well with Random Walk Metropolis
  - ▶ **Chib-Jeliazkov estimator** works well with independence MH

# CHOOSING YOUR MEASUREMENTS

Figure A.6a: Log likelihood contours in the  $\{\tilde{\phi}_s, \rho_\phi\}$ -space, using all observable variables

# CHOOSING YOUR MEASUREMENTS

Figure A.6b: Log likelihood contours in the  $\{\tilde{\phi}_s, \rho_\phi\}$ -space, only using the real exchange rate

# COMMENTS

- ▶ RAMSES I used **calibrated measurement error variances** (diagonal  $\mathbf{R}$ ). Ad hoc ... Calibrated measurement errors should depend on the properties of the measured variables. But, results were not very sensitive to the calibrated values.
- ▶ We also tried to estimate  $\mathbf{R}$  (assuming it to be diagonal). Worked, but didn't change the posterior of the deep parameters very much.
- ▶ Measurement errors **do** have a crucial effect on the **marginal likelihood** comparison to reduced form models such as BVARs (and DSGE-VARs) [2].
- ▶ Posteriors can be bimodal (intrinsic and extrinsic frictions can produce similar fits). Not a problem per se, but the MCMC needs to visit both modes in correct proportions.

# COMMENTS

- ▶ DSGEs are relatively misspecified models. Marginal likelihoods are not (so) useful. Impulse responses, predictive checks and traditional forecasting evaluations more relevant.
- ▶ Multivariate measures of forecasting performance (log determinant MSFE matrix) can be **very** sensitive to poor predictions in **very** specific directions of the data. [3]
